Introduction

1.1 Introduction 8
1.2 Overview 8
1.3 Usage 9
1.1 Introduction

The Signaling System 7 (SS7) Installation and Configuration Manual describes the installation, configuration, and operation of the SS7 Message Transfer Part (MTP) and optional ISDN User Part (ISUP), Telephone User Part (TUP), Signaling Connection Control Part (SCCP), and Transaction Capabilities Application Part (TCAP) software for the TX Communication Processors under Windows NT/Windows 2000 and versions of UNIX.

1.2 Overview

The SS7 distribution software contains the TX Base/Device Driver and the SS7 software packages. This software contains a variety of components which facilitate the development of sophisticated SS7-based systems and applications.

The following components are installed with the TX Base/Device Driver:

- The TX device driver for the selected host operating system.
- The `tdmcfg` utility for configuring the characteristics of T1/E1 channels and assigning T1/E1 and/or MVIP/H.100/H.110 bus channels to SS7 ports.
- The `cplot` utility for downloading executable code and configuration data onto the board.
- The TX cpk/os operating system and related executables which are downloaded to the TX board at boot time.
- The `txalarm` utility which collects alarms from the TX board(s), displays them on a console screen, and optionally copies them to a disk file. This utility is also distributed in source form as a guide for developers integrating the TX board alarms into their own alarm monitoring systems.
Each of the SS7 software packages contains some or all of the following components.

- The SS7 protocol layer (MTP, SCCP, TCAP, ISUP, and/or TUP) executables which are downloaded to the TX board at boot time.
- Application program interfaces (APIs) - header files and libraries - for developing SS7-based applications. Separate APIs are typically provided for signaling applications (call processing applications and transaction processing applications) and management applications (configuration, control, monitoring, and statistics).
- Sample applications illustrating use of the APIs.
- A configuration utility for downloading configuration information from a text file on the host disk to the protocol layer task running on the TX board. Configuration utilities are also provided in source form as an example of management API usage for configuration.
- Sample configuration files for ANSI and/or ITU-T configurations.
- A management utility for controlling, monitoring, and collecting statistics on the SS7 protocol layer. Like the configuration utilities, the management utilities are also provided in source form to illustrate use of the management APIs.

1.3 Usage

Use of the SS7 software requires the following steps:

1. Install the SS7 software.
2. If you use T1/E1 or MVIP/H.100/H.110 bus channels as the physical SS7 links, configure which streams/timeslots will carry the SS7 links.
3. Set up your SS7 MTP layer 3 configuration and, optionally, SCCP, TCAP, ISUP, and/or TUP configurations.
4. Download the TX board with the appropriate software and configurations.
Chapter 2

SS7 Software Installation

2.1 Before Starting Installation   12

2.2 General Installation Steps   12
   2.2.1 Installing the Base/Device Driver Package   12
   2.2.2 Installing the SS7 MTP and Optional Software Packages   13
2.1 Before Starting Installation

Before you begin the software installation process you must have the following information available for each TX ISA communications processor in your system:

- The IRQ number assigned to the board with the on-board IRQ Select jumper
- The memory address assigned to the board via the on-board Memory Address Select DIP switches

2.2 General Installation Steps

The following installation steps are required, regardless of the target operating system:

1. Install the TX Base/Device Driver package.
2. Install the SS7 MTP package.
3. Install any optional SS7 software components (SCCP layer, TCAP layer, ISUP layer, and/or TUP layer).
4. Reboot the system to start the device driver.

2.2.1 Installing the Base/Device Driver Package

The Base/Device Driver package must be installed before any of the SS7 software packages. The exact procedure for installing and configuring the TX device driver varies for each supported operating system. See the software installation instructions for information on the installation of the Base/Device driver package for your operating system.
2.2.2 Installing the SS7 MTP and Optional Software Packages

The MTP layer should be the first SS7 package installed after the Base/Device Driver package has been installed. Again, the exact procedure for installing and configuring SS7 software packages varies for each supported operating system.

Once the MTP layer is installed, any of the other optional SS7 software packages may be installed at any time and in any order. It is not necessary to reboot your system after installing any of the SS7 software packages. The system only needs to be rebooted after installing the Base/Device Driver package or after modifying the device driver configuration.

Once started, the installation procedure for all the SS7 packages is self-explanatory. No SS7 configuration information is required at installation time. The installation process simply copies the necessary files for each package - board executables, API libraries, configuration and management utilities, sample configuration files, and sample applications - to the appropriate location on the target system.

WARNING: If you are installing a new release over an existing installation and you have modified any of the sample configuration files or sample applications for any of the SS7 layers, please make sure they have been renamed, moved to another directory, or otherwise adequately backed up before starting the new installation. These files may be overwritten without warning by the new release installation.
Chapter 3

Getting Started

3.1 Introduction  16
3.2 Modifying the Sample Configuration Files  18
  3.2.1 The TDM Configuration File  18
  3.2.2 The MTP 3 Configuration File  20
3.3 Starting the txalarm Utility  21
3.4 Downloading the Boards With ss7load  22
3.5 Monitoring Link Status Through txalarm  24
3.6 Troubleshooting Link Problems Through txalarm  25
### 3.1 Introduction

The sample configuration files shipped with each of the SS7 software packages are set up to illustrate a simple SS7 configuration between two TX boards in a single PC chassis, connected by a single SS7 link, as illustrated in **Figure 1**:

**Figure 1. Sample SS7 Test Setup**

**Note:** You cannot run the SS7 link test described in this section by looping back two ports on a single TX board. A minimum of two TX boards, or one board and a separate piece of SS7 test equipment capable of emulating an SS7 node up through MTP layer 3, are required.
Depending on the physical hardware configuration of your TX boards, the physical SS7 link interface between the boards may be one of the following interface types:

- A single timeslot on one of the T1/E1 ports (requires TX Dual-T1 or Dual-E1 daughterboard or rear I/O transition board)
- A single timeslot on the MVIP/H.100/H.110 bus
- A V.35 serial link (requires TX V.35 serial daughterboard or rear I/O transition board)

The sample configuration files shipped on the installation media assume a single SS7 link running in timeslot zero on T1 port A. If you use E1 rather than T1, or the MVIP/H.100/H.110 bus or V.35 serial links, you will have to make changes to the sample configuration files.

Once the appropriate physical connections are completed, the following steps are used to bring the link into service:

1. Make any necessary changes to the TDM and MTP3 configuration files.
2. Start the `txalarm` utility on your host PC to monitor the status of the links.
3. Download both boards using the `ss7load` download script.
4. Check the `txalarm` output to see that the link comes into service on both boards.
5. Troubleshoot any problems indicated in the `txalarm` output.

These steps are described in the following sections.

## 3.2 Modifying the Sample Configuration Files

If your hardware configuration does not match the configuration assumed by the sample configuration files, you’ll have to modify the samples to get the SS7 link up and running.

All sample configuration files are found in the \nms\tx\config\ directory for Windows NT/Windows 2000 and in the /opt/nmstx/etc directory on UNIX systems.

### 3.2.1 The TDM Configuration File

The sample TDM configuration files under Windows NT/Windows 2000 are named tdmcp1.txt and tdmcp2.txt (or tdmcp1.cfg and tdmcp2.cfg under UNIX). The sample TDM configuration file for board one is shown here:

<table>
<thead>
<tr>
<th>CLOCK</th>
<th>NETA</th>
</tr>
</thead>
<tbody>
<tr>
<td>SEC8K</td>
<td>NONE</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>T1</td>
<td>Framing</td>
</tr>
<tr>
<td>--</td>
<td>--------</td>
</tr>
<tr>
<td>T1A</td>
<td>ESF</td>
</tr>
<tr>
<td>T1B</td>
<td>ESF</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Port</th>
<th>Stream</th>
<th>Channel</th>
<th>Count</th>
<th>Direction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port1</td>
<td>T1A</td>
<td>Channel0</td>
<td>Count1</td>
<td>Standard</td>
</tr>
</tbody>
</table>

The sample TDM configuration file presents a simple example of the most common type of TX board use. When a single TX board is present in a chassis, the tdmcp1.txt file can be used to configure a board with a Dual T1 daughterboard or rear I/O transition board. This configuration specifies CLOCK NETA, indicating the clock recovered from T1A should be presented onto the MVIP/H.100/H.110 bus. When two TX boards are present in a chassis, tdmcp2.txt can be used to configure board two. Board two is configured with the T1s set as Loop Master. This causes board two to use its internal oscillator as the clock source for both T1s. This board is also configured with CLOCK BUS, indicating the TDM clock should be taken from the MVIP/H.100/H.110 bus. These configuration files will require various changes to be made when the boards are being loaded for purposes other than initial testing.
The following list provides some common TDM configuration changes required for different hardware configurations. For more details on the content of the TDM configuration file, and how to compile it for use by the TX board kernel, see Chapter 4.

- If you use the V.35 serial interface rather than TDM ports, you do not need to modify the TDM configuration, as it won’t be used. You do, however, need to change the SS7 link definition in the MTP 3 configuration file. See Section 3.2.2, The MTP 3 Configuration File for more information.

- The sample TDM configuration assumes T1 ports. If you are using the E1 interface instead, you must change the T1 parameters line to reflect proper E1 parameters and you must change the channel timeslot number assigned as Port\text{1} to a timeslot other than zero (timeslot zero is used solely for framing on E1 ports and cannot be used to transport data such as SS7).

- The sample configuration files contain commented out sections that define other types of TDM connections. Examples of connections over E1, MVIP, and H.100/H.110 are included.

- Clocking control may also need to be modified based on the specific environment. The example for CP #1 assumes to be receiving clock from T1A. This implies that T1A is connected to another T1 device that is acting as Loop Master. The example for CP #2 causes that CP to act as the Loop Master for both T1 interfaces. If this is not the desired clocking configuration then the \texttt{CLOCK} and/or \texttt{Loop Master} fields should be modified.

Once the TDM configuration file has been modified, it must be compiled into a binary image with the \texttt{tdmcfg} utility before downloading the board. See Section 4.3, Configuration Binary File Generation for details.
### 3.2.2 The MTP 3 Configuration File

The sample MTP 3 configuration files are named `mtp3cp1.cfg` (for board one) and `mtp3cp2.cfg` (for board two). The MTP 3 configuration file is a longer file, containing definitions of many of the attributes of the SS7 MTP layers: general attributes, link definitions, link set definitions, and route definitions. The MTP 3 configuration is described in detail in Section 5.2, *The MTP Configuration*.

The link one definition from the sample MTP3 configuration for board one is shown below:

```plaintext
# Link Parameters
#----------------- 
LINK T1     # T<n> for T1/E1/MVIP, S<n> for serial (V.35)
LINK_SET 1
ADJACENT_DPC 1.1.2  # Board 2
LINK_SLC 0
MAX_CREDIT 127
MESSAGE_SIZE 272 
#
# Level 2 parameters
#
LSSU_LEN 2
END
```

For this test, the only change that should be necessary to the MTP 3 configuration is if you use V.35 serial links rather TDM links. In this case you must change the link one definition from port T1 to port S1. Also you must specify one side of the link (board one) as the DCE and the other side of the link (board two) as the DTE. Make sure that the link configured as the DCE also has its V.35 POD port strapped for DCE operation. Likewise, the link configured as the DTE must have its V.35 pod port strapped for DTE operation. See the appropriate hardware manual for details on configuring the V.35 pod.
3.3 Starting the txalarm Utility

The `txalarm` utility captures alarm messages from the boards, displays them on the screen, and optionally saves them to a disk file. It is the primary tool for monitoring what is happening on the link as you download the board and try to bring the link up.

The `txalarm` utility is best run from a separate window (“DOS window” in Windows NT/Windows 2000, or a “command window” when using a UNIX desktop-style user interface. It is run with the command:

```
txalarm [-f filename]
```

where the `-f` option, if present, specifies the file to which alarms are copied (in addition to displaying them).

The output from `txalarm` looks similar to this:

```
<01/07/1998 16:17:04> mtp   1 18180 MTP3 Link 1 Down
```

<table>
<thead>
<tr>
<th>Timestamp</th>
<th>Task</th>
<th>Board Number</th>
<th>Alarm Number</th>
<th>Alarm Text</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;01/07/1998 16:17:04&gt;</td>
<td>mtp</td>
<td>1</td>
<td>18180</td>
<td>MTP3 Link 1 Down</td>
</tr>
</tbody>
</table>

```
### 3.4 Downloading the Boards With ss7load

Once the configuration files are set and the txalarm utility is running, the TX boards can be downloaded with the software and configuration. The **ss7load** download script file is included to perform this action.

The **ss7load** script contains all the commands required to download the necessary software and configuration files to the TX boards. This script is resides in the following locations:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Directory Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows NT and Windows 2000</td>
<td><code>\nms\tx\bin\ss7load.bat</code></td>
</tr>
<tr>
<td>UNIX</td>
<td><code>//opt/nmstx/bin/ss7load</code></td>
</tr>
</tbody>
</table>

At installation time, the **ss7load** script contains commands to download and configure all the SS7 layers. Only the MTP layer is activated, however; the others are “commented out”. To enable any optional SS7 layers you have installed you must edit **ss7load** and remove the comment symbols from the desired layers.

**Note:** Superuser permissions are required to edit the **ss7load** file on UNIX systems.

**ss7load** expects a single parameter on the command line: the board number. For the two-board test described here, the sequence would look something like this (user input is shown in **bold** type):

```
prompt> ss7load 1
CPMODEL V1.0: Copyright 1998, NMS Communications
Board #1 is a TX2000
Loading: E.0 TX2000 Kernel (c)1996-1997 NMS Communications, Inc. 2/10/97
Loading: diag2000    Version C.1.0 12/10/97
Loading: inf         Version C.4.0 12/10/97
Loading: mvip        Version A.1.0 12/10/97
Loading: t1e1mgr     Version A.1.0 12/10/97
Loading: mtp         Version B.3.0 01/14/98
mtp2cfg: sample MTP2 configuration application version B.1.0 Jan 14 1998
mtp3cfg: sample MTP3 configuration application version B.3.0 Jan 14 1998
prompt> ss7load 2
```
The following is output from `txalarm` when `ss7load` is executed for board one. An equivalent set of alarms is received from board two when it is downloaded.

```
<12/05/1997 15:51:58> mtp 1   1 Registering MTP Layer 2
<12/05/1997 15:51:58> mtp 1   1 Registering MTP Layer 3

<12/05/1997 15:51:58> mtp 1   1 MTP3: Ready...
```
3.5 Monitoring Link Status Through txalarm

Once the boards have been downloaded, they will repeatedly attempt to align the links (bring up through layer 2). Once link alignment has been achieved by MTP layer 2, MTP layer 3 will attempt to bring the links into service through an exchange of signaling link test messages (SLTMs) with its peer MTP 3 on the other board. Once this signaling link test is successfully completed, an alarm is generated from each board indicating that the link is up (in service). A typical alarm sequence for successful link startup looks like this:

```
<01/09/1998 09:54:21> mtp 1 1 Flushing Buffers (OPC=0)
<01/09/1998 09:54:21> mtp 1 1 Starting Alignment
<01/09/1998 09:54:21> mtp 1 1 IAC Rx SIO
<01/09/1998 09:54:21> mtp 1 1 IAC Rx SIO
<01/09/1998 09:54:21> mtp 1 1 Rx SIE (9)
<01/09/1998 09:54:22> mtp 1 1 ALIGN TIMER 4 EXPIRED (Link Aligned)
<01/09/1998 09:54:22> mtp 1 1 Setting link 0 ACTIVE in SigLinkAvail
<01/09/1998 09:54:22> mtp 1 1 DPC 0.1.2 is now ACCESSABLE (LinkSet 1)
<01/09/1998 09:54:22> mtp 1 1 Setting link 0 ACTIVE in TrafLinkAvail
<01/09/1998 09:54:22> mtp 1 1 Setting link 0 ACTIVE from SLTA
<01/09/1998 09:54:22> mtp 1 1 8179 MTP3 Link 0 Up
<01/09/1998 09:54:21> mtp 2 1 Flushing Buffers (OPC=0)
<01/09/1998 09:54:21> mtp 2 1 Starting Alignment
<01/09/1998 09:54:21> mtp 2 1 IAC Rx SIO
<01/09/1998 09:54:21> mtp 2 1 IAC Rx SIO
<01/09/1998 09:54:21> mtp 2 1 Rx SIE (9)
<01/09/1998 09:54:22> mtp 2 1 ALIGN TIMER 4 EXPIRED (Link Aligned)
<01/09/1998 09:54:22> mtp 2 1 Setting link 0 ACTIVE in SigLinkAvail
<01/09/1998 09:54:22> mtp 2 1 DPC 0.1.2 is now ACCESSABLE (LinkSet 1)
<01/09/1998 09:54:22> mtp 2 1 Setting link 0 ACTIVE in TrafLinkAvail
<01/09/1998 09:54:22> mtp 2 1 Setting link 0 ACTIVE from SLTA
<01/09/1998 09:54:22> mtp 2 1 8179 MTP3 Link 0 Up
```
3.6 Troubleshooting Link Problems Through txalarm

If the link does not come into service shortly after being downloaded, the cause of the problem may frequently be determined from the txalarm output. The primary cause of link initialization failures are physical connection problems. Physical connection problems are usually indicated by a repeated sequence of alarms indicating that Align Timer 2 Expired and Alignment not possible as shown in the following example:

```
<01/09/1998 09:49:58> mtp  2  1 Starting Alignment
<01/09/1998 09:49:58> mtp  2  1 Layer l: AERM Threshold Reached
<01/09/1998 09:49:58> mtp  2  1 Alignment Aborting
<01/09/1998 09:50:10> mtp  2  1 ALIGN TIMER 2 EXPIRED, QLen=0 iacSt=8
<01/09/1998 09:50:10> mtp  2  1 LinkFailure : Alignment Not Possible
<01/09/1998 09:50:10> mtp  2  1 Flushing Buffers (OPC=0)
<01/09/1998 09:50:11> mtp  2  1 8180 MTP3 Link 0 Down
```

There are many possible causes of physical link connection problems. The following list illustrates a few of the possible causes:

- Missing or loose cable connections between the T1/E1 ports.
- Missing bus cable when one board is deriving clocking from the MVIP/H.100/H.110 bus.
- Incorrect clocking configuration between the two boards (both boards driving MVIP/H.100/H.110 bus clocks, neither driving MVIP/H.100/H.110 bus clocks, clocking not synchronized to T1/E1 port).
- Mismatched channel timeslot assignments between the two boards.
- Missing or loose cable connections between the boards and V.35 pods or between the two V.35 pods.
- Incorrect V.35 DCE/DTE configuration: both boards configured as DTE (the default), DCE side of link plugged into V.35 pod strapped for DTE operation or vice versa.
The link may also align successfully at layer 2 but fail the signaling link test at layer 3. This results in an alarm indicating that Align Timer 4 Expired (Link Aligned) followed by an MTP alarm indicating that the link is down, as shown in the following example:

```
<01/09/1998 09:54:21> mtp  1  1 Starting Alignment
<01/09/1998 09:54:21> mtp  1  1 IAC Rx SIO
<01/09/1998 09:54:21> mtp  1  1 IAC Rx SIO
<01/09/1998 09:54:21> mtp  1  1 Rx SIE (9)
<01/09/1998 09:54:22> mtp  1  1 ALIGN TIMER 4 EXPIRED (Link Aligned)
<01/09/1998 09:54:22> mtp  1  1 8180 MTP3 Link 0 Down
```

This failure is almost always caused by one of two configuration errors.

- The point codes assigned to each of the boards in the MTP 3 configuration file do not properly refer to each other.

- The link select code assigned to the link in the MTP 3 configuration file (LINK_SLC) of one board does not exactly match the link select code assigned to the same link in the MTP 3 configuration file of the second board.
Chapter 4

Configuring TDM Bus Physical Interfaces

4.1 Overview  28  
4.2 TDM Configuration Creation  28  
4.2.1 T1/E1 Configuration Options  30  
4.2.2 MVIP/H.100/H.110 Bus Timing Options  32  
4.2.3 TDM Port Configuration  33  
4.3 Configuration Binary File Generation  34  
4.4 Configuration Download  34
4.1 Overview

If you use T1/E1 or MVIP/H.100/H.110 bus channels (also known as TDM channels) as the physical SS7 links, you must configure which streams/timeslots will carry the SS7 links. This requires the following steps:

1. Create a text file describing your T1/E1 and/or MVIP/H.100/H.110 bus configuration (a sample configuration file is provided with the distribution software).

2. Run the `tdmcfg` utility to create a binary TDM configuration file suitable for downloading to the TX board.

3. Add a command to the download script to download the TDM configuration to the TX board (see Chapter 5).

These steps are described in the following subsections. Each TX board in a system requires its own separate TDM configuration file.

4.2 TDM Configuration Creation

Dedicated data channels from the T1/E1/MVIP/H.100/H.110 interfaces are pre-configured by creating an off-line database and downloading it to the CPK kernel at download time. Off-line database creation consists of creating the configuration text file, generating the configuration binary file, and loading the configuration (binary) file.

*Note:* Each TX communications processor in a system must have its own separate dedicated data channel configuration database.
A text file (hereafter referred to as the `tdmcfg.txt` file) is prepared, which contains a description of each dedicated data channel: the "port" that it is assigned to, the T1/E1 or MVIP/H.100/H.110 stream that it occupies, the first timeslot on that stream that it occupies, the number of timeslots used, and the direction (described below). The `tdmcfg.txt` file also configures the clocking associated with the MVIP/H.100/H.110 bus interface as well as the configuration of the T1/E1 interfaces. The following shows a sample `tdmcfg.txt` file.

```plaintext

```
4.2.1 T1/E1 Configuration Options

The T1/E1 configuration line consists of an identifier indicating which circuit (A or B) is being configured followed by parameters specifying the Framing, Line Encoding, Line Buildout, Robbed Bit signaling, and Loop Master configuration for this circuit.

**Framing Options** - Determines the framing format to be used for this T1/E1 circuit.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>Do not configure this T1/E1 circuit.</td>
</tr>
<tr>
<td>ESF</td>
<td>[T1] Extended Superframe Format.</td>
</tr>
<tr>
<td>CCS</td>
<td>[E1] Frame alignment only (no multiframe alignment).</td>
</tr>
<tr>
<td>CAS</td>
<td>[E1] Standard frame alignment with <em>Channel Associated Signaling</em> (timeslot 16) multiframe alignment (no CRC4).</td>
</tr>
<tr>
<td>CCSCRC4</td>
<td>[E1] Standard frame alignment with CRC4 multiframe alignment (no CAS).</td>
</tr>
<tr>
<td>CASCRC4</td>
<td>[E1] Standard frame alignment with both <em>Channel Associated Signaling</em> (timeslot 16) and CRC4 multiframe alignment.</td>
</tr>
</tbody>
</table>

**Encoding Options** - Determines line encoding and zero suppression mechanism to be used for this circuit.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOZCS</td>
<td>[T1 or E1] AMI encoding with no zero code suppression.</td>
</tr>
<tr>
<td>B7ZS</td>
<td>[T1] Bit Seven Zero Stuffing.</td>
</tr>
<tr>
<td>B8ZS</td>
<td>[T1] Bipolar Eight Zero Substitution.</td>
</tr>
<tr>
<td>HDB3</td>
<td>[E1] High Density Bipolar (order 3) encoding.</td>
</tr>
</tbody>
</table>
Buildout Options - Determines line buildout to be used for this T1/E1 circuit.

<table>
<thead>
<tr>
<th></th>
<th>T1</th>
<th>E1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0:</td>
<td>0-133 Feet</td>
<td></td>
</tr>
<tr>
<td>1:</td>
<td>133-266 Feet</td>
<td></td>
</tr>
<tr>
<td>2:</td>
<td>266-399 Feet</td>
<td></td>
</tr>
<tr>
<td>3:</td>
<td>399-533 Feet</td>
<td></td>
</tr>
<tr>
<td>4:</td>
<td>533-655 Feet</td>
<td>120 Ohm Normal With Protection Resistors [This value is the default for E1]</td>
</tr>
</tbody>
</table>

Robbed Bit Flag - Set to **TRUE** or **FALSE**, indicates whether Robbed Bit Signaling is used by the TX board on this T1/E1 circuit.

Loop Master Flag - Set to **TRUE** or **FALSE**, indicates whether this T1/E1 interface is the timing source for this circuit.
4.2.2 MVIP/H.100/H.110 Bus Timing Options

A TX communications processor may either provide an MVIP, H.100, or H.110 TDM bus interface. This interface is generally referred to as MVIP in the following example. The bus timing entry describes the clocking configuration for the MVIP bus clock signals (/C4, /F0, C2) and Secondary 8K clock signals. The clocking configuration statement syntax is:

CLOCK clockmode
SEC8K sec8kmode

where clockmode is one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BUS</td>
<td>MVIP adapter gets its timing signals from the MVIP bus (Default).</td>
</tr>
<tr>
<td>MASTER</td>
<td>MVIP adapter drives the MVIP bus clock signals from its internal clock.</td>
</tr>
<tr>
<td>SEC8K</td>
<td>The MVIP adapter drives the MVIP bus clock signals referenced from the MVIP Secondary 8K signal.</td>
</tr>
<tr>
<td>NETA</td>
<td>The MVIP adapter drives the MVIP bus clock signals and derives this timing from T1 interface A.</td>
</tr>
<tr>
<td>NETB</td>
<td>The MVIP adapter drives the MVIP bus clock signals and derives this timing from T1 interface B.</td>
</tr>
</tbody>
</table>

and sec8kmode is one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MASTER</td>
<td>The MVIP adapter drives the SEC8K clock signals from its internal clock.</td>
</tr>
<tr>
<td>NETA</td>
<td>The MVIP adapter drives the SEC8K clock signals and derives this timing from T1 interface A.</td>
</tr>
<tr>
<td>NETB</td>
<td>The MVIP adapter drives the SEC8K clock signals and derives this timing from T1 interface B.</td>
</tr>
<tr>
<td>NONE</td>
<td>The SEC8K clock is not driven by the MVIP adapter (Default).</td>
</tr>
</tbody>
</table>
4.2.3 TDM Port Configuration

The channel definition entry describes the characteristics of each dedicated data channel. Channels are always defined as full-duplex connections. For the MVIP bus, stream $n$ is always paired with stream $n+8$. For the H.100/H.110 bus, stream $n$ is always paired with stream $n+1$.

By default, an MVIP stream numbering scheme is assumed. For H.100 and H.110 systems, add the following entry in the TDM configuration file to specify that the stream numbering is based on an H.100/H.110 numbering scheme:

```
BUS H100
```

The following table describes each field in the TDM configuration file:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port $n$</strong></td>
<td>Identifies the port assigned to this data channel, where $n$ is an integer in the range $1 \leq n \leq maxPorts$ and $maxPorts$ depends on the hardware configuration. This port number is used when configuring other TX communication software products to utilize this data channel.</td>
</tr>
</tbody>
</table>
| **Stream $n$** | Identifies the MVIP stream that this channel occupies.  
  - MVIP Stream numbers are 0-7  
  - H.100/H.110 Stream numbers are 0-30 (even numbers only)  
  - T1/E1 Streams are identified by name (T1A, E1A, T1B, E1B)  
  - T1/E1 B Stream number is 18 |
| **Channel $n$** | Refers to the starting channel number.  
  - MVIP uses channel numbers 0-31  
  - H.100/H.110 uses channel numbers 0-127  
  - T1 uses channel numbers 0-23  
  - E1 uses channel numbers 1-31 (0 is used for framing) |
| **Count $n$** | Identifies the number of timeslots that make up this channel. Valid range is 1-32.  
  *Note:* A special case exists for a 56 Kb or a 48 Kb subrate on a single DSo.  
  If count is set to 56 or 48, the indicated subrate is allocated. |
| **Direction** | Identifies the direction of bus signals for MVIP/H.100/H.110 channels. |
Possible values are:

<table>
<thead>
<tr>
<th>STANDARD:</th>
<th>MVIP</th>
<th>H.100</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stream 0</td>
<td>DS00 = input</td>
<td>Stream 0</td>
</tr>
<tr>
<td></td>
<td>DS10 = output</td>
<td>(Stream 1)</td>
</tr>
<tr>
<td>Stream 1</td>
<td>DS01 = input</td>
<td>Stream 2</td>
</tr>
<tr>
<td></td>
<td>DS11 = output</td>
<td>(Stream 3)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>REVERSE:</th>
<th>MVIP</th>
<th>H.100</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stream 0</td>
<td>DS00 = output</td>
<td>Stream 0</td>
</tr>
<tr>
<td></td>
<td>DS10 = input</td>
<td>(Stream 1)</td>
</tr>
<tr>
<td>Stream 1</td>
<td>DS00 = output</td>
<td>Stream 2</td>
</tr>
<tr>
<td></td>
<td>DS11 = input</td>
<td>(Stream 3)</td>
</tr>
</tbody>
</table>

Note: Reverse is only applicable to MVIP/H.100/H.110 channels; T1/E1 channels should always be specified as Standard.

### 4.3 Configuration Binary File Generation

The configuration binary file is generated by running the configuration utility on the text file. This is done with the command:

```
tdmcfg -i filename
```

The TDM Configuration utility will generate 2 files:

- `filename.bin` Binary configuration file
- `filename.dbg` Text representation of the above binary file

### 4.4 Configuration Download

The configuration is downloaded using the standard `cplot` utility with the `-g` option.

```
cplot -g TDM -f tdmcfg binary file name [-c board number]
```

This must be downloaded before any tasks which might attempt to use the specified data channels.

Note: The TX board must have been previously loaded or reset (PCI boards) before performing this action.

5.1 Introduction to the MTP Layer

The SS7 MTP layer 3 has two primary functions.

- Message routing and distribution
- Signaling network management

Message routing and distribution includes both the routing of outgoing messages to their specified destinations and the distribution of incoming messages to the appropriate user part or application. The SS7 MTP implementation uses a flexible configuration capability to support a wide variety of network routing and addressing requirements.

Signaling network management’s job is to reconfigure the signaling network as needed to maintain signaling capability in the case of failures or congestion. This includes redirecting traffic away from failed links and/or signaling points (SPs), restoring traffic to restored links/SPs, and exchanging route status with adjacent SPs. The MTP 3 layer supports all required ANSI and ITU-T network management procedures without intervention from the user parts/applications.

The primary objects represented by MTP layer 3 are signaling links, routes, linksets, and Network Service Access Points (NSAPs).

Links define physical signaling links between the TX board and the adjacent signaling points. One link configuration must be performed for each physical signaling link. The attributes of a link include the point code of the adjacent signaling point, protocol variant employed on the link (ITU-T or ANSI), point code length, maximum packet length, various timer values, membership in a linkset, and others.

Linksets are groups of from one to 16 links that directly connect two signaling points. Although a linkset usually contains all parallel signaling links between 2 SPs, it is possible to define parallel link sets. Each signaling link defined is assigned membership in exactly one link set.

Routes specify the destination signaling points (or sub-networks (clusters) when route masks are employed) that are accessible from the target node. Each route is assigned a direction - up or down. One up route is required for the actual point code assigned to the signaling point being configured and for each point code that is to be emulated. Up routes are used to identify incoming messages that are to be routed up to the applications/user parts. One down route is required for each remote signaling point/network/cluster that is to be accessible from the SP being configured.
Down routes are used to route outgoing messages to the appropriate signaling links. Each down route is assigned to each linkset that can be used to reach that destination. Each link set within the route's associated combined linkset may have an optional priority assigned, such that MTP routing will choose the highest priority available link set when routing an outgoing packet to a particular destination.

Note: Priorities range from 0 (highest) to 15 (lowest) for both links and linksets. Priorities must be assigned starting at zero and incremented by one for each lower priority (there can be no gaps in priority assignment).

Figure 2 illustrates the relationship between links, linksets, and routes.

Figure 2. Links, Link Sets, and Routes
Network service access points (NSAPs) define the SS7 user parts, or applications, which are users of the MTP service. Each NSAP is associated with one user part or application (as identified by the service indicator field of a message) and one protocol variant (ITU-T or ANSI). Figure 3 illustrates the concept of NSAPs:

![Network Service Access Points (NSAPs)](image)

If multiple protocol variants are configured on the same MTP 3 instance (same board) then two NSAPs are required for each user part: one for ANSI, one for ITU-T. In this case, a single user part/application may associate itself with both NSAPs for that service, or separate user part/applications may be used for each protocol variant.
5.2 The MTP Configuration

The SS7 distribution software contains two MTP utility programs - \texttt{mtp3cfg} and \texttt{mtp2cfg} - which read a text configuration file and downloads the specified configuration to the MTP task on the TX board, typically as part of the download sequence.

The general format of the MTP configuration file is shown below:

\begin{verbatim}
<General Configuration Parameters>
END
<Link 0 definition>
<Layer 3 Parameters>
<Layer 2 Parameters>
END
<Link (n - 1) definition>
<Layer 3 Parameters>
<Layer 2 Parameters>
END
<NSAP 0 definition>
<NSAP Parameters>
END
<NSAP (n - 1) definition>
<NSAP Parameters>
END
<Route 0 definition>
<Route Parameters>
END
<Route (n - 1) definition>
<Route Parameters>
END
<Link Set 1 definition>
<Link Set Parameters>
END
<Link Set n definition>
<Link Set Parameters>
END
\end{verbatim}

Use of the \texttt{mtp3cfg} utility is required for specifying the MTP layer 3 configuration. Use of the \texttt{mtp2cfg} utility is optional. It scans only the links definition section of the MTP configuration file and need only be run if it is necessary to override the default MTP layer 2 parameters assigned to each link (the default values for the MTP layer 2 parameters are specified in Section 5.5).

The sample \texttt{ss7load} script, provided with the distribution software, executes both MTP configuration utilities.
5.2.1 General Configuration Section

The general configuration parameters define and control the general operation of the signaling point (SP) implemented by the TX SS7 software. General configuration parameters include the type of signaling point being constructed (SP or STP), the point code assigned to the signaling point, the MTP 3 timer resolution, the values for various SP-level timers, and the maximum number of other configurable elements (user parts (NSAPs), links, link sets, routes) to control memory allocation. The general parameters are configured once at board download time, before any other entities are configured. The board must be re-downloaded to change any of the general configuration parameters.

5.2.2 Links Configuration Section

The links configuration section defines the physical signaling links between the TX board and the adjacent signaling points. It contains a link configuration block for each SS7 link. The links section is scanned by both the MTP layer 3 and MTP layer 2 configuration utilities (this is the only section scanned by the MTP layer 2 configuration utility). Each link configuration block is comprised of both layer 3 parameters and layer 2 parameters, in any order.

The layer 3 configurable attributes of a link include the link number, the port and port type (serial or TDM) assigned to a link, the point code of the adjacent signaling point, protocol variant employed on the link (ITU-T or ANSI), point code length, maximum packet length, various timer values, membership in a linkset, and others.

The layer 2 configurable attributes include all layer 2 timers, the LSSU length to be used on the link, and the interface type - DCE or DTE - and baud rate for V.35 serial links.

5.2.3 Network Service Access Points (NSAPs) Section

Network service access points (NSAPs) define the SS7 user parts, or applications, which are users of the MTP service. The configurable attributes of NSAPs include the protocol variant (ITU-T or ANSI) and point code length supported by the user part/application associated with the NSAP, and the maximum number of user part/application messages to be queued (at each of the four possible message priority levels) when flow control between the MTP 3 and application is in effect.
5.2.4 Route Definition Section

Routes specify the destination signaling points (or sub-networks, for example, clusters when route masks are employed) that are accessible from the node being configured. Each route is assigned a direction - up or down. Up routes are used to identify incoming messages that are to be routed up to the applications/user parts. One down route is required for each remote signaling point/network/cluster that is to be accessible from the SP being configured. Down routes are used to route outgoing messages to the appropriate signaling links.

Other configurable attributes of routes include the destination point code, the protocol variant in use at the destination SP/cluster/network, and various timers associated with MTP route management.

5.2.5 Linkset Definition Section

The linkset configuration section contains a configuration block defining each linkset between the TX board and the adjacent signaling points. Linksets are numbered from 1 to MAX_LINKSETS (MAX_LINKSETS is a general configuration section parameter). The configurable attributes of a linkset include the point code of the adjacent signaling point, the list of routes that are accessible via that linkset, and the number of links to attempt to keep active.
5.3 Sample MTP Configuration File

The SS7 distribution software contains MTP sample configuration files for both ANSI and ITU-T configurations. The sample ANSI configuration for board one in the two-board sample test configuration appears as follows:

```
#------------------------------------------------
# Overall MTP3 Parameters
#------------------------------------------------
NODE_TYPE STP       # choose STP [routing] or SP [non-routing]
PC_FORMAT DFLT      # Point code format: DFLT (8.8.8) / INTL (3.8.3) / JNTT (7.4.5)

5.4 MTP Configuration Considerations

The MTP 3 layer can be configured as either a signal transfer point (STP) or as a signaling end point, referred to simply as an SP. The primary difference between STP operation and SP operation is in the handling of messages received from signaling links by the MTP 3 layer but addressed to other destinations.

When configured as an STP, the MTP 3 layer will search for an outbound route to the message’s destination and, if found, will route the message over an outbound link. When configured as an SP, the MTP 3 layer will discard such messages.

When configured as an STP, the MTP 3 layer will also perform the additional signaling route management procedures required of an STP. These primarily involve notifying adjacent SPs when they must no longer route messages to a particular destination through that STP due to failures or congestion (transfer prohibited/restricted), and notifying them again when normal communication with the concerned destination is restored (transfer allowed).

5.4.1 Configuring Routes to Non-Adjacent Nodes

The sample configuration shown above involves only a single adjacent signaling point directly connected to the TX board. You may also need to configure non-adjacent signaling points (for example, those that are not directly connected to the MTP 3 layer but are accessible through a signaling point that is directly connected), such as in the network configuration shown in Figure 4. The procedure for configuring a non-adjacent signaling point is as follows:

1. Configure all links, link sets, and routes to adjacent signaling points, such as the STPs in Figure 4, as described in the sample configuration files.

2. Add a route entry (direction down) for the non-adjacent SP, specifying its point code as the destination of the route.

3. Add the route number for the non-adjacent SP to the link set entry for each link set that may be used to reach the non-adjacent destination.
Since the non-adjacent SP in Figure 4 (point code 1.1.200) is accessible from both STPs the route entry for 1.1.200 is added to the link set definitions for both linksets one and two. Note that since the STPs in Figure 4 are cross-connected, the route to each STP is also added to both linksets one and two since STP 1.1.1 may be reached directly through linkset two or indirectly through linkset one via STP 1.1.0. A sample MTP configuration file for this network configuration appears as follows:
<General Parameters>

# Link Parameters

LINK                      T1       # Link 0 to STP 1.1.0
LINK_SET                  1
ADJACENT_DPC              1.1.0
END

LINK                      T1       # Link 1 to STP 1.1.1
LINK_SET                  2
ADJACENT_DPC              1.1.1
END

# Routing Parameters

# Route UP from network to applications on this node

ROUTE                     0
DPC                       1.1.100  # this node
DIRECTION                 UP
END

ROUTE                     1
DPC                       1.1.0    # STP 1.1.0
END

ROUTE                     2
DPC                       1.1.1    # STP 1.1.1
END

ROUTE                     3
DPC                       1.1.200  # Route to non-adjacent 1.1.200
END

ROUTE_NUMBER              2
ROUTE_NUMBER              3
END

LINK_SET_DESCRIPTOR       2
ADJACENT_DPC              1.1.1    # link set to STP 1.1.1
ROUTE_NUMBER              1
ROUTE_NUMBER              2
ROUTE_NUMBER              3
END
5.4.2 Using Priorities

Priority levels range from 0 (highest) to 15 (lowest). If priorities are used, you must start with zero for the highest priority linkset for a given route and thereafter increment by one for lower priority linksets for that route. There cannot be any gaps in the priority assigned for a given route, although equal priorities are allowed.

Linkset priorities can be used to assure that the shortest path will be taken by a message, when available. Using Figure 2 as an example, we would want messages destined for STP 1.1.0 to use linkset one (when available) and not linkset two, which would require an extra hop through STP 1.1.1. Similarly, for messages to STP 1.1.1 we would always want to use linkset two, if available.

To assure that linkset one will always be chosen for messages to STP 1.1.0, if available, we can assign a higher priority to route one in linkset one. Likewise, we can do the same for STP 1.1.1, route two, and linkset two. Linkset priorities are defined in the configuration file by placing a comma and the priority after a route number in the linkset definition.

Note: Route number one (STP 1.1.0) is assigned priority zero in linkset one and priority one in linkset two, indicating linkset one is higher priority than linkset two for messages destined for STP 1.1.0. Route number two (STP 1.1.1) is assigned the reverse priorities. Routes three and four have no priorities assigned to them, indicating both linksets are of equal priority for reaching SP 1.1.200 and SP 1.1.201. When a priority is not specified, the default of zero (highest) is assigned. Therefore specifying 3,0 and 4,0 in both linksets would have the same results as not specifying a priority level at all. They are configured as equal priority because no matter which linkset is chosen, a message to either 1.1.200 or 1.1.201 will require two hops.
The following configuration excerpt shows how to specify linkset priorities for Figure 2:

```
# Routing Parameters
#
ROUTE 0
DPC 1.1.100  # this node
DIRECTION UP
END
#
ROUTE 1
DPC 1.1.0  # STP 1.1.0
END
#
ROUTE 2
DPC 1.1.1  # STP 1.1.1
END
#
ROUTE 3
DPC 1.1.200  # SP 1.1.200
ADJACENT_ROUTE FALSE  # Route to non-adjacent SP 1.1.200
END
#
ROUTE 4
DPC 1.1.201  # STP 1.1.201
ADJACENT_ROUTE FALSE  # Route to non-adjacent SP 1.1.201
END
#
# Link Set Parameters
#
LINK_SET_DESCRIPTOR 1
ADJACENT_DPC 1.1.0
ROUTE_NUMBER 1,0
ROUTE_NUMBER 2,1
ROUTE_NUMBER 3
ROUTE_NUMBER 4
END

LINK_SET_DESCRIPTOR 2
ADJACENT_DPC 1.1.1
ROUTE_NUMBER 1,1
ROUTE_NUMBER 2,0
ROUTE_NUMBER 3
ROUTE_NUMBER 4
END
```
5.4.3 Using Routing Masks

The MTP 3 layer allows for the use of routing masks to help decrease the size of the routing tables that must be configured. Routing masks are bit masks that specify a subset of a destination point code to be matched against the routing table when searching for a route for either an inbound or outbound message.

Routing masks may be used to implement network and cluster routing in ANSI networks. For example, consider the following network diagram (Figure 5). Rather than specifying explicit routes to each of the seven remote SPs, routing masks and routes can be used (note that all point codes and routing masks, regardless of point code length, are stored internally as 32-bit unsigned integers). Routing masks are also useful when implementing server-type applications, such as Service Control Points (SCPs), where it is impractical to pre-configure the point codes of all possible requester signaling points.

Note: Routing masks are global to all links, link sets, and user parts, and are applied to both incoming and outgoing messages.

![Figure 5. Using Routing Masks for Simpler Route Tables](image-url)
Typical routing masks used in ANSI networks for routing based on Network and/or Cluster IDs are shown in the table below.

**Note:** Routing masks are applied to a message in the order that they appear in the MTP configuration file and the first matching mask/route is the one selected.

<table>
<thead>
<tr>
<th>Routing Mask</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xFFFFFFFF</td>
<td>Always specify exact match as first mask</td>
</tr>
<tr>
<td>0xFFFF0000</td>
<td>Match on just network ID last</td>
</tr>
<tr>
<td>0xFFFF0000</td>
<td>Match on network ID + cluster ID next</td>
</tr>
</tbody>
</table>
The following example shows a partial MTP configuration file for the network diagram provided earlier:

```
MAX_ROUTE_MASKS          3
ROUTE_MASK               0xFFFFFFFF     # always specify exact match 1st
ROUTE_MASK               0xFFFFFFFF00    # cluster mask next
ROUTE_MASK               0xFFFF0000      # network mask next

<Link Parameters>
#Routing Parameters
ROUTE                    0
DPC                      1.1.100        # Route up to this node
DIRECTION                UP
END
# ROUTE 1
DPC                      1.1.255        # Explicit route to STP 1.1.255
END
# ROUTE 2
DPC                      1.2.255        # Explicit route to STP 1.2.255
END
# ROUTE 3
DPC                      2.1.255        # Explicit route to STP 2.1.255
END
# ROUTE 4
DPC                      1.1.0          # Partial route to cluster 1.1.x
END
# ROUTE 5
DPC                      1.2.0          # Partial route to cluster 1.2.x
END
# ROUTE 6
DPC                      2.0.0          # Partial route to network 2.x.y
END
# Link set Parameters
LINK_SET_DESCRIPTOR      1
ADJACENT_DPC             1.1.255        # link set to STP 1.1.255
ROUTE_NUMBER             1             # explicit route to 1.1.255
ROUTE_NUMBER             4             # cluster route to 1.1.x
END
# LINK_SET_DESCRIPTOR    2
ADJACENT_DPC             1.2.255        # link set to STP 1.2.255
ROUTE_NUMBER             2             # explicit route to 1.2.255
ROUTE_NUMBER             5             # cluster route to 1.2.x
END
```
Although the previous example is specific to ANSI networks, routing masks can be applied equally to other networks (ITU-T based networks with 14- or 24-bit point codes) to reduce the size of routing tables.

When using routing masks and “partial-match” routes, the following guidelines should be adhered to:

- Always configure an UP route with the TX board’s point code first.
- Always configure an explicit route to each node directly connected to the TX board.
- Always configure an “exact match” routing mask - 0xffffffff - before any “partial match” routing masks.
5.4.4 Considerations for Configuring for Japan-NTT Protocol Variant

The following guidelines should be followed when configuring the MTP layer for Japan-NTT network operation.

1. The `LINK_TYPE` attribute for all links, NSAPs, and route entries should be set to `JNTT`.

2. The point code length for links and NSAPs will default to 16 once the `LINK_TYPE` is set to `JNTT`; there is no need to specify this explicitly. If desired for documentation purposes, however, the point code length can be explicitly set to 16 (the only supported value for JNTT link type) in the link and NSAP configurations.

3. 16-bit point codes may be specified in either hex or in "x.y.z" dotted notation. Hex point codes must be specified in the same order that they are transmitted on the link; that is, the U-code in the most significant seven bits, the S-code in the next four bits, and the M-code in the least significant five bits. In order to specify J-NTT 16-bit point codes in "x.y.z" notation, the `PC_FORMAT` parameter in the MTP 3 general configuration section must be set to the value `JNTT`.

For example:

```
PC_FORMAT     JNTT
...
LINK          S1
LINK_TYPE     JNTT
ADJACENT_DPC  1.1.2
...
```

Is equivalent to:

```
...  
LINK          S1
LINK_TYPE     JNTT
ADJACENT_DPC  0x421
...
```
5.4.5 Sample MTP Configuration File for Japan-NTT Protocol Variant

A sample MTP3 configuration file for two V.35 serial links with the JNTT protocol variant is shown below.

```
#-----------------------------------------------------
# Sample MTP3 configuration for J-NTT protocol variant

5.5 MTP Configuration Parameters Reference

There are five major sections of the MTP configuration file - general parameters, link parameters, network SAP parameters, routing parameters, and link-set parameters.

5.5.1 General Parameters

The following table lists all configurable parameters in the MTP 3 general configuration section and their default values. The default values for all timers at the MTP 3 level are in tenths of a second. A configuration value of zero for a timer disables that timer. The MTP3_TIMER_RES parameter may be used to specify whether timer values being overridden in the MTP 3 configuration file are specified in seconds or tenths of a second.

Note: The PC_FORMAT attribute applies to all point codes throughout the entire MTP configuration file.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Default</th>
<th>Range</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>PC_FORMAT</td>
<td>DEFAULT</td>
<td>DEFAULT [DFLT], INTER-NATIONAL [INTL], JNTT</td>
<td>Point Codes are interpreted/displayed as 24-bit 8.8.8 values.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Point Codes are interpreted/displayed as 14-bit 3.8.3 values.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Point codes are interpreted/displayed as 16-bit mcode.scode.ucode</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>values with the U-code in the most significant 7 bits, the S-code in the next 4 bits, and the M-code in the least significant 5 bits.</td>
</tr>
<tr>
<td>POINT_CODE</td>
<td>none</td>
<td>N/A</td>
<td>The Point Code of this node, specified in dot notation (such as 2.45.76) or a hex number (such as 0x101). This is a required parameter.</td>
</tr>
<tr>

<td>SP</td>
</tr>
</tbody>
</table>

Note: The PC_FORMAT attribute applies to all point codes throughout the entire MTP configuration file.
### General Parameters

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Default</th>
<th>Range</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>POINT_CODE2</td>
<td>N/A</td>
<td></td>
<td>Alternate point code for this node when interfacing to both ANSI and ITU-T networks from same board (in that case, specify the ITU-T point code in POINT_CODE parameter and ANSI point code here).</td>
</tr>
<tr>
<td>MTP3_TIMER_RES</td>
<td>SECONDS</td>
<td>TENTHS, SECONDS</td>
<td>Specifies whether timer values in the configuration file are in seconds or tenths of a second.</td>
</tr>
<tr>
<td>RESTART_REQUIRED</td>
<td>TRUE</td>
<td>TRUE / YES FALSE / NO</td>
<td>Set to TRUE if full restart procedure required whenever node becomes accessible.</td>
</tr>
<tr>
<td>VALIDATE_SSF</td>
<td>TRUE</td>
<td>TRUE / YES FALSE / NO</td>
<td>When set to true, MTP 3 will validate incoming MTP 3 signaling network management (SNM) and test (SLTM/SLTA) messages; i.e., those whose SSF does not match the value configured for the link the message was received on will be rejected; otherwise the SSF will not be checked on incoming MTP 3 management or test messages - any SSF value will be accepted. MTP 3 will not validate the SSF in any incoming or outgoing user part messages.</td>
</tr>
<tr>
<td>DISABLE_UPU</td>
<td>FALSE</td>
<td>TRUE/YES FALSE/NO</td>
<td>If set to TRUE, MTP will never send a User Part Unavailable message.</td>
</tr>
<tr>
<td>MAX_LINKS</td>
<td>4</td>
<td>1 to 16</td>
<td>Maximum number of physical links (actual maximum depends on TX board model and hardware configuration).</td>
</tr>
<tr>
<td>MAX_USERS</td>
<td>2</td>
<td>1 to 64</td>
<td>Maximum number of MTP 3 users (user parts).</td>
</tr>
<tr>
<td>MAX_ROUTES</td>
<td>32</td>
<td>1 to 32767</td>
<td>Maximum number of routes.</td>
</tr>
<tr>
<td>MAX_ROUTE_ENTRIES</td>
<td>64</td>
<td>1 to 32767</td>
<td>Maximum number of route instances (logical max is MAX_LINKS * MAX_ROUTES, but can be decreased).</td>

<td>Maximum number of link sets supported.</td>
</tr>
<tr>
<td>MAX_ROUTE_MASKS</td>
<td>0</td>
<td>0 to 8</td>
<td>Maximum number of routing masks. If zero, then all destination point code in outgoing messages must exactly match a point code in a route entry.</td>
</tr>
<tr>
<td>ROUTE_MASK</td>
<td>None</td>
<td>0x00 to 0xFFFFFFFF</td>
<td>A routing mask to be applied to destination point code before matching against route table entries. Can be used to reduce number of routes that must be configured or when remote destination point codes are not known at configuration time (that is, a database server). Multiple ROUTE MASKs may be specified; they are applied in the order that they appear in the configuration file.</td>
</tr>
<tr>
<td>TIMER_T15</td>
<td>30</td>
<td>0 to 65535</td>
<td>Wait to start/repeat route set congestion test.</td>
</tr>
<tr>
<td>TIMER_T16</td>
<td>20</td>
<td>0 to 65535</td>
<td>Wait for route set congestion status update.</td>
</tr>
<tr>
<td>TIMER_T18_ITU</td>
<td>300</td>
<td>1 to 65535</td>
<td>ITU restart timer for an STP during which links are restarted and TFA, TFR, and TFP messages are received.</td>
</tr>
<tr>
<td>TIMER_T20_ITU</td>
<td>600</td>
<td>1 to 65535</td>
<td>ITU overall restart timer.</td>

<td>ANSI restart timer to limit sending of TFPs and TFRs in response to unexpected TRA or TRW.</td>
</tr>
<tr>
<td>END</td>
<td></td>
<td></td>
<td>Marks end of this route definition.</td>
</tr>
</tbody>
</table>
## 5.5.5 Link Set Parameters

The following parameters are valid for defining a link set:

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Default</th>
<th>Range</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>LINK_SET_DESCRIPTOR</td>
<td>none</td>
<td>1 to MAX_LINKSETS</td>
<td>The Link Set identifier number; referenced in LINK_SET parameter of each individual link.</td>
</tr>
<tr>
<td>ADJACENT_DPC</td>
<td>none</td>
<td>N/A</td>
<td>The point of the adjacent SP that terminates this link set. Use &quot;dotted&quot; notation, 2.45.76 or hex number, 0x101.</td>
</tr>
<tr>
<td>MAX_ACTIVE_LINKS</td>
<td>16</td>
<td>1 to 16</td>
<td>Target number of links in this link set to keep active at any given time.</td>
</tr>
<tr>
<td>ROUTE_NUMBER</td>
<td>none</td>
<td>0 to MAX_ROUTES</td>
<td>A route number and optional priority associated with a destination that can be reached through this link set; up to 16 route numbers may be specified per link set. The same route number may be assigned to multiple link sets. The optional priority associated with the route number is relative to other link sets which also contain this route number.</td>
</tr>
<tr>
<td>END</td>
<td></td>
<td></td>
<td>Marks end of this Link Set definition.</td>
</tr>
</tbody>
</table>

Chapter 6

SS7 ISUP Configuration

6.1 Introduction to the ISUP Layer 72
6.2 The ISUP Configuration 74
6.3 Sample ISUP Configuration File 75
6.4 ISUP Configuration Parameters Reference 77
   6.4.1 General Parameters 77
   6.4.2 Service Access Point (SAP) Definition 80
   6.4.3 Network Service Access Point (NSAP) Definition 82
   6.4.4 Circuit Group Definitions 83
6.1 Introduction to the ISUP Layer

The SS7 ISDN User Part (ISUP) software provides the interface for applications to establish, maintain, and clear circuit switched connections via the SS7 network, in accordance with the CCITT Q.761-Q.764 and ANSI T1.113 (1988 and 1992) recommendations. The ISUP layer is also responsible for circuit [group] management, such as blocking, unblocking, and resetting of circuits and circuit groups.

The configurable objects represented by the ISUP layer are Circuits, User Service Access Points (User SAPs), Network Service Access Points (NSAPs), and Routes. In addition, the ISUP layer has a set of general configuration parameters which define the behavior of the ISUP layer as a whole.

Circuits are the physical bearer circuits controlled by the ISUP layer. Circuits are identified by both a circuit index and a circuit identification code (CIC). The circuit index is a number unique across all circuits configured on a particular TX board. This number has only local significance - it is used between the ISUP layer and the local call processing application to identify a particular circuit.

The CIC (usually called the kick, or kick code) is used between signaling points (i.e., the ISUP layer and the far exchange that terminates the other end of the circuit) to uniquely identify a particular circuit. The CIC must be configured at both ends of the circuit to identify the exact same bearer facility, for example, the same T1 span and timeslot. CICs need not be unique across circuits that terminate on different far exchanges.

Circuits are specified in the ISUP configuration file in groups. A group is one or more circuits with contiguous circuit indexes and contiguous CICs that terminate on the same far exchange and have common characteristics. A single circuit group will frequently be used to represent all the timeslots on a single T1 or E1 span, for example. When defining a circuit group, only the circuit index and CIC of the first circuit in the group, along with the number of circuits in the group, are specified. The ISUP layer derives the circuit index and CIC for subsequent circuits since they are considered to be contiguous. The starting circuit index and starting CIC for a group need not be the same value.

User SAPs define the interface between the ISUP layer and the user applications.

Note: This release of the SS7 ISUP layer supports only a single user application; therefore only one user SAP should be configured.
The NSAP defines the interface between the ISUP layer and the MTP layer. It identifies the MTP network SAP to used by the ISUP layer, allowing multiple user parts (for example, ISUP and SCCP) to share access to the MTP layer services. Figure 6 illustrates the concept of user SAPs and NSAPs.

![ISUP User SAPs and Network SAPs](image)

**Figure 6. ISUP User SAPs and Network SAPs**

Routes can be configured to allow the ISUP layer to select the circuit for an outgoing call based on the called party number. A route typically specifies a routing prefix such as the first three digits or first six digits of a directory number, to match against the called party number. Typically the application itself will perform circuit selection for outgoing calls, since it must perform any hardware setup and/or switching on the physical circuit. In this case, there is no need to configure any routes.
6.2 The ISUP Configuration

The SS7 ISUP software contains a utility program, `isupcfg`, which reads a text configuration file and downloads the specified configuration to the ISUP task on the TX board, typically as part of the download sequence.

The general format of the ISUP configuration file is as follows:

```
<General Configuration Parameters>
<User SAP definition>
<SAP Parameters>
END
<NSAP definition>
<NSAP Parameters>
END
<NSAP (n - 1) definition>
<NSAP Parameters>
END
<Route 0 definition>
<Route Parameters>
END
<Route (n - 1) definition>
<Route Parameters>
END
<Circuit Group 1 definition>
<Circuit Group Parameters>
END
<Circuit Group n definition>
<Circuit Group Parameters>
END
```
6.3 Sample ISUP Configuration File

The ISUP software contains sample configuration files for both ANSI and ITU-T configurations. These configurations may be used in conjunction with the MTP sample configuration files to test ISUP applications using two TX boards in a back-to-back arrangement (see Chapter 3). The following example shows the sample ANSI configuration file for one board.

```
# General configuration parameters

6.4 ISUP Configuration Parameters Reference

There are five major sections of the ISUP configuration file: general parameters, user SAP definition, network SAP definition, routes, and circuits.

6.4.1 General Parameters

The general parameters control the overall operation of the ISUP layer process.

Note: All ISUP timer values are in seconds.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Default</th>
<th>Range</th>
<th>Usage</th>
</tr>

6.4.2 Service Access Point (SAP) Definition

The SAP definition defines the characteristics of the ISUP service presented to the user application(s).

Note: This release of the ISUP layer software allows for configuration of only a single ISUP user SAP. Therefore, only one application may use the ISUP service at a time. Timer default values in parenthesis are ITU values.

<table>
<thead>
<tr>
<th>Parameter Name</th>

<td>NATIONAL, INTERNATIONAL, 0-3, RESERVED, SPARE</td>
<td>The value used in the sub-service field (SSF) of the service information octet in outgoing ISUP messages on this MTP interface.</td>
</tr>
<tr>
<td>MTP_SAP</td>
<td>0</td>
<td>0 to 255</td>
<td>MTP Service Access Point to which to bind ISUP. This must match one of the NSAP numbers defined in the MTP configuration file; also must be unique among all user parts that use the MTP service (that is., SCCP, TUP).</td>
</tr>
<tr>
<td>END</td>
<td>N/A?</td>
<td>N/A</td>
<td>Marks the end of the NSAP section.</td>
</tr>
</tbody>
</table>
6.4.4 Circuit Group Definitions

The circuit group definitions specify the characteristics of each of the circuit groups to be managed by the ISUP layer. This includes the circuit identification codes (CICs), destination point code (DPC) at the other end of the circuits, and circuit type (incoming, outgoing, or both). One entry is made for each circuit group.

*Note:* Timer default values in parenthesis are ITU values.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Default</th>
<th>Range</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>CIRCUIT</td>
<td>none</td>
<td>1 to MAX_CIRCUITS</td>
<td>The number of the first circuit in this group. Circuits in this group are numbered from this value to (value + NUM_CIRCUITS - 1). This range must be unique for all circuits defined. This value is used by the application and the ISUP layer to identify circuits, but has no meaning to the far exchange.</td>
</tr>
<tr>
<td>CIC</td>
<td>1</td>
<td>0 to 4095</td>
<td>The circuit identification code (CIC) of the first circuit in this group. Circuits in this group are assigned CICs from this value to (value + NUM_CIRCUITS - 1). The number range must agree with the CICs assigned to this circuit group at the far exchange.</td>
</tr>
<tr>
<td>DPC</td>
<td>none</td>
<td>N/A</td>
<td>The destination point code to which this circuit group connects.</td>
</tr>
<tr>
<td>CIRCUIT_TYPE</td>
<td>INCOMING</td>
<td>INCOMING, OUTGOING, BOTHWAY</td>
<td>Direction of calls allowed on this circuit group.</td>
</tr>

7.1 Introduction to the SCCP Layer

The SS7 SCCP layer builds on the services of the MTP layer to provide SS7 applications with a higher level transport subsystem. In particular the SCCP layer adds the following services to those provided by the MTP layers:

- The ability to address individual applications or databases, known as subsystems, at a signaling point through a SCCP-level address consisting of a point code and a subsystem number.
- An OSI-like connectionless transport service.
- An OSI-like connection-oriented transport service.
- An address translation mechanism, called global title translation, which can translate a string of digits (such as a telephone number or mobile identification number) into a point code and/or subsystem number, isolating applications from changes in the physical SS7 network structure.
- A subsystem management layer which tracks the status of targeted subsystems at particular signaling points, known as concerned signaling points, and can optionally associate a backup signaling point with a subsystem for high availability applications.

Applications access these services either directly from the SCCP layer or indirectly through the TCAP layer.

The SS7 SCCP layer implements these services through the configuration of several entities: User Service Access Points, Network Service Access Points, Routes, and Address Translations, in addition to general configuration parameters which control the operation of the SCCP layer as a whole.

*User Service Access Points (User SAPs)* define the interface between the user applications and the SCCP layer. One user SAP is defined for each application using the SCCP layer services. A user SAP is associated with a single subsystem number and protocol variant (ANSI or ITU-T). The user SAP defines whether the application is replicated on another node for reliability purposes, and lists any concerned point codes (nodes which must be notified of any change in the status of the application). Figure 7 illustrates the concept of user SAPs. Note that when the application interfaces to the TCAP layer, the TCAP SAPs map one-for-one with a SCCP user SAP.
Network SAPs define the interface between the SCCP layer and the MTP layer 3. One network SAP is defined for each MTP 3 layer interface that the SCCP layer uses. Typically the SCCP layer has only a single network SAP, although if the same system supports multiple protocol variants (ANSI and ITU-T), the SCCP layer would have a separate network SAP for each switch type.

One route is defined for each destination signaling point that the SCCP layer may be used to access. The route defines the destination point code of that signaling point and each subsystem of interest at that signaling point as well as any backup point codes which replicate those subsystems. If the SCCP default routing feature is employed, all routing is deferred to the MTP layers and no SCCP routes need not be defined. This is described in detail in Section 7.4.

Address Translation entries define how the SCCP layer is to translate and/or route between global titles, point codes, and subsystem numbers. Global title translation is described in more detail in Section 7.5.

---

Figure 7. SCCP User Service Access Points
Figure 8 illustrates the relationship between the various configurable entities.

Figure 8. SCCP Configurable Entities
7.2 The SCCP Configuration

The SS7 SCCP software contains a utility program, \texttt{sccpcfg}, which reads a text configuration file and downloads the specified configuration to the SCCP task on the TX board, typically as part of the download sequence.

The general format of the SCCP configuration file is provided here:

```
<General Configuration Parameters>
<User SAP 0 definition>
 <SAP Parameters>
END
<User SAP n-1 definition>
 <SAP Parameters>
END
<NSAP definition>
 <NSAP Parameters>
END
<Address Translation definition>
 <Address Translation Parameters>
END
<Route 0 definition>
 <Route Parameters>
END
<Route m-1 definition>
 <Route Parameters>
END
```
7.3 Sample SCCP Configuration File

The SCCP distribution software contains sample configuration files for both ANSI and ITU-T configurations. These configurations may be used in conjunction with the MTP sample configuration files to test SCCP applications using two TX boards in a back-to-back arrangement (see Chapter 3). The following example shows the sample ANSI configuration file for one board.

Note: All SCCP timer values are in seconds; a timer value of zero disables that timer.

```
# Sample SCCP configuration file for the following configuration
#
# General:
#   4 user APPs max
#   1 MTP3 network SAP
#   all others general defaults
# User SAPs:
#   ANSI-92, 1.1.2 is concerned PC
# Network Saps:
#   ANSI, point code = 1.1.1
# Routes:
#   1 to 1.1.2, SSNs 3 & 4, 1.1.2 is concerned PC
# Address translations:
#   8477069701 = far point code, SSN 3, 8477069700
#   847xxxxxxx = far point code, SSN 4
#
# General Configuration Section
MAX_USERS         4         # Max SCCP user applications

7.4 Using Default Routing

The **SCCP Default Routing** feature allows routing of SCCP packets generated by local applications (either directly via the SCCP API or through the SS7 TCAP layer) to signaling points whose point codes and subsystem numbers are not pre-configured.

This feature is primarily intended for applications that will act as databases, or servers, in an SS7 network and cannot be pre-configured with the point codes of all clients that will access the server. This feature may also be suitable for other SCCP and/or TCAP based applications that do not require the signaling point and subsystem management features of the SCCP management functions, such as replicated subsystems.

7.4.1 Introduction

When default routing is enabled, the SCCP layer attempts to deliver messages for which it has no explicit route entry by relying solely on the MTP layer routing. This applies to all classes of SCCP messages: connectionless, connection-oriented, and management. This effectively disables all SCCP management functionality for those remote signaling points/subsystems without explicit routes. This has several ramifications, which are described in Section 7.4.5, **SCCP Limitations When Default Routing is Enabled**.

When default routing is enabled, it may still be desirable to pre-configure routes to certain known destinations, such as adjacent STPs/ translators, or other remote subsystems which are replicated and require the SCCP management procedures for routing to backup signaling points in case of outages or congestion.

7.4.2 Enabling Default Routing

Default routing is disabled by default. To enable default routing, the following statement is added to the general configuration parameters section of the SCCP configuration file.

```
DEF_ROUTING TRUE   # Default Routing (FALSE = OFF, TRUE = ON)
```
7.4.3 Impact of Default Routing on SCCP Message Routing

Routing of outbound messages by the SCCP layer is now performed as follows.

1. Global title translation, if necessary, is performed on the outbound message.

2. The SCCP layer checks for an explicit route to the destination point code. If an explicit route exists, the status of the destination signaling point and subsystem, if known, are checked. If the destination signaling point is active and the destination subsystem available (or unknown - such as routing by global title), the message is passed to the MTP 3 layer for delivery. If the signaling point is not accessible or the subsystem is unavailable, standard routing failure treatment is applied.

3. If no explicit route exists for the destination point code and default routing is disabled, standard routing failure treatment is applied.

4. If no explicit route exists for the destination point code and default routing is enabled, the message is passed to MTP 3 for delivery. If the MTP 3 layer is unable to deliver the message for any reason, the message is discarded and no notification is given to the application that originated the message.

7.4.4 Impact of Default Routing on SCCP Management

The SCCP layer does not attempt to track the status of signaling points and subsystems which are not explicitly defined with route entries. Subsystem prohibited (SSP) and subsystem allowed (SSA) messages received for signaling points with no explicit route entry are ignored. Likewise, pause, resume, and remote user unavailable indications from the MTP 3 layer regarding signaling points with no explicit route entry are ignored. In effect, signaling points/subsystems with no explicit route entry are always considered available at the SCCP layer.

Subsystem testing is applied only to explicitly configured signaling points and subsystems (that is, SST messages are never sent to destinations with no explicit route entry defined).

If a subsystem test (SST) message is received from a signaling point which is not explicitly configured with a route entry, the appropriate response (SSA if the local subsystem is available, no response if the local subsystem is prohibited or unequipped) is returned, provided that the MTP 3 layer is able to route the response to that signaling point.
If the SCCP layer receives a message from an unknown (not explicitly configured) remote signaling point for a local subsystem which is either prohibited or unequipped, a subsystem prohibited (SSP) message is returned to the originating signaling point, provided that the MTP 3 layer is able to route to that signaling point. The appropriate message return (connectionless) or connection refusal (connection request) procedures are also performed.

7.4.5 SCCP Limitations When Default Routing is Enabled

As described above, use of default routing effectively disables the SCCP layer management functions for those signaling points not explicitly configured with route entries. This section summarizes many of the limitations which result from the use of default routing.

- If a local subsystem is to be replicated and take advantage of the SCCP layer’s ability to route incoming messages to the backup signaling point when the local application is unavailable, an explicit route to the backup signaling point must be configured.

- If a remote subsystem is to be replicated and take advantage of the SCCP layer’s ability to route outgoing messages to the backup signaling point when the primary signaling point or subsystem is unavailable, explicit routes to both the primary and backup signaling points must be configured.

- If a local application (SCCP or TCAP API user) wishes to receive status indications for a remote signaling point/subsystem when it becomes available, unavailable, or congested then an explicit route entry must be configured for each such remote signaling point and it must be listed as a concerned point code in the application’s user SAP configuration.

- If a remote subsystem is to receive automatic SSP and SSA messages when a local application (SCCP or TCAP API user) declares itself unavailable/available then an explicit route entry must be configured for each such remote signaling point and it must be listed as a concerned point code in the application’s user SAP configuration.

-Subsystem prohibited (SSP) and subsystem allowed (SSA) messages received for signaling points with no explicit route entry are ignored. In effect, signaling points/subsystems with no explicit route entry are always considered available at the SCCP layer.
7.5 Configuring Global Title Translations

The SS7 SCCP layer supports global title translation, a feature which allows applications to address messages with a string of digits, such as a telephone number or a mobile identification number, and rely on the network configuration to route the message to the correct destination signaling point and subsystem. This can help isolate applications from changes in the network structure, such as when a particular network database is moved from one signaling point code to another. This feature is available for both applications accessing the SCCP layer directly and for applications using the SCCP layer indirectly through the TCAP layer.

The SCCP layer can translate a global title into its final destination address (point code and subsystem number) or, more likely, into the address of a gateway STP. A gateway STP is typically an STP containing a global title translation capability which acts as the entry point to a network for all requests originating from outside the network. In either case, the global title digits may be carried through in the translated address for subsequent translation by the gateway STP or analysis by the destination application.

Consider the example network diagram shown in Figure 9. The SCCP application uses both the 800 number translation and 900 number translation services provided by the databases shown.

![Figure 9. Example Global Title Translation Network Diagram](image-url)
In this case, the network addresses (point codes) of these databases are not known to the node; only the address of the gateway is configured in the SS7 configuration files.

When the application sends a request for either an 800 number or 900 number translation, it generates a SCCP request (or TCAP request) with the 10-digit 800 or 900 number to be translated as the global title digits and the routing indicator field set to *route by global title*. The application does not include a point code or subsystem number in the destination address.

The following SCCP sample configuration illustrates the configuration of the address translation.

- The ADDRESS_MASK parameter for the user SAP that corresponds to this application is set to **FFFF000000**. This causes the SCCP layer to choose the first address translation entry whose first 3 digits match the first three global title digits in the message whose address is being translated.

- The configured address translation for both 800 and 900 numbers specifies the point code of the gateway STP, which will perform subsequent global title translation on the message’s destination address to insert the actual point code of the appropriate database. A subsystem number is also included here, although it could also be inserted by the gateway STP.

- The configured address translation for both 800 and 900 numbers specifies a routing indicator of *route by global title* to indicate to the gateway STP to perform global title translation; it also indicates that the original global digits are *not* to be replaced in the outgoing message so that the gateway STP may perform the subsequent translation.
The following example illustrates ANSI address formats:

```
# Sample configuration of Global Title Translation
< ... General Parameters >
# User SAP configuration for example application
USER_SAP          0           # Application 1
SWITCH_TYPE       ANSI92      # protocol variant
CONC_PC           2.199.0     # Gateway STP
ADDR_MASK         FFF0000000 # match 1st 3 global title digits
END               # User application 0

# Address Translations: 800XXXXXXX numbers
ADDRESS           800         # global title - incoming
REPLACE_GLT       FALSE       # retain global title in message
SWITCH_TYPE       ANSI        # Address format - one of ITU, ANSI
NI_IND            NATIONAL    # national address format
DPC               2.199.0     # translated destination point code
SSN               254         # translated subsystem number
ROUTING_IND       GLT         # set outgoing routing flag to GLT
END               # of address translation for 800xxxxxxx

# Address Translations: 900XXXXXXX numbers
ADDRESS           900         # global title - incoming
REPLACE_GLT       FALSE       # retain global title in message
SWITCH_TYPE       ANSI        # Address format - one of ITU, ANSI
NI_IND            NATIONAL    # national address format
DPC               2.199.0     # translated destination point code
SSN               254         # translated subsystem number
ROUTING_IND       GLT         # set outgoing routing flag to GLT
END               # of address translation for 900xxxxxxx
```

The Address Masks have the following properties:

- Incoming messages use the Address Mask(s) defined in the Network SAP section of the SCCP configuration file.
- Outgoing messages use the Address Mask(s) defined in the User SAP section of the SCCP configuration file.
- Up to four Address Masks can be defined in each Network SAP or User SAP section.
- Address Masks are applied in the order they are defined in the configuration file. Therefore, list the most specific mask first, and the most general mask last.
7.6 SCCP Configuration Reference

There are five major sections of the SCCP configuration file - general parameters, user SAP definition, network SAP definition, routes, and circuits.

7.6.1 General Parameters

The general parameters configuration section defines the operational characteristics of the SCCP layer, such as upper bounds for internal data structures (these determine the amount of memory used by the SCCP layer), queue thresholds, and various protocol timer values. It is the first section of the configuration file.

7.6.2 User Service Access Point (USAP) Definitions

One user SAP is defined for each application using the SCCP layer services. A user SAP is associated with a single subsystem number and switch type (ANSI88, ANSI92, ANSI96, ITU88, or ITU92). The user SAP defines whether the application is replicated on another node for reliability purposes, and lists any concerned point codes (nodes which must be notified of any change in the availability of the application).

</tr>
</tbody>
</table>
### Field Name | Default | Range | Description
--- | --- | --- | ---
INACT_CONTROL | False | True /False 0/1 Yes/No | When true, enables SCCP inactivity timing on connections associated with this SAP, allowing SCCP to detect and clear connections that the application has lost track of. Application must handle Connection Inactivity Indication event and respond with Connection Inactivity Response if this feature is enabled.

CONG_THRESH_1 | 600 | 1 to 2000 | Number of messages outstanding to a higher level task (such as TCAP) or a user application at which inbound congestion level 1 starts.

CONG_THRESH_2 | 900 | 1 to 2000 | Number of messages outstanding to a higher level task (such as TCAP) or a user application at which inbound congestion level 2 starts.

CONG_THRESH_3 | 1200 | 1 to 2000 | Number of messages outstanding to a higher level task (such as TCAP) or a user application at which inbound congestion level 3 starts.

END | | | This is a required parameter that denotes end of the section.

**Note:** Address masks are ASCII strings containing a 0 (zero) or ε in each character position to determine whether the corresponding global title digit is used in the match. For example, the string 000ffffffff will result in ignoring the 1st three digits and comparing only last 7 digits when searching the global title table for a match. Similarly, the string eeff will compare only the first 3 digits to determine a match.
7.6.3 Network Service Access Point (NSAP) Definitions

The Network SAP defines the point at which the SCCP layer accesses the network (MTP 3) layer. One network SAP is defined for each switch type (ANSI or ITU-T) supported. The NSAP number assigned in this section (NSAP number statement) must match a valid NSAP number defined in the NSAPs section (NSAP number statement) of the MTP 3 configuration file.

Note: If both the SCCP and ISUP layers are used on the same board, the SCCP layer cannot be assigned to MTP3 NSAP 0 (zero); ISUP always uses this NSAP.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
### Field Name  Default  Range  Description

| ADDR_MASK  | FFF...F  | N/A  | Ascii string describing which digits of global title to match on when performing global title translation (refer to the note below and also note from User SAP section). Up to four ADDR_MASK entries are allowed per Network SAP. |
|(31,345,961,355)  |  |  |  |
| MAX_HOPS  | 10  | 1 to 15  | Hop count value to be used when returning undeliverable incoming messages back to the source of the message. |
| SCCP_NI_IND  | 0 (ITU)  | 0 or 1  | Used by SCCP for national/international indicator in called/calling party address parameter of outgoing SCCP management messages. |
|  | 1 (ANSI)  |  |  |
| END  |  |  | This is a required parameter that denotes end of the section. |

**Note:** The Network SAP address mask is used only when providing global translation for *incoming* messages (those received from the network). For messages originated by an application on this node, the User SAP address mask is used.
7.6.4 Address Translation Definitions

Address entries define how the SCCP layer is to translate and/or route between global titles, point codes, and subsystem numbers. A global title may translate into one of the following:

- A point code and subsystem number (use GT_FORMAT 0)
- Another global title only (in this case the message to be routed must include a destination point code in addition to the incoming global title)
- Another global title + point code
- Another global title + subsystem number (in this case the message to be routed must include a destination point code in addition to the incoming global title)
- Another global title + point code + subsystem number

Multiple address translations may be configured, up to the MAX_ADDRS value specified in the general parameters section.

</tbody>
</table>
7.6.5 Route Definitions

A route configuration entry defines a point code (and its subsystems) known to this node. A route entry must be defined for each point code and switch type to which this node may send SCCP messages.

Note: Each route definition contains one or more subsystem definitions, each of which spans multiple lines and is terminated with an END statement. Each route definition as a whole is also terminated with an END statement. Mismatched END statements are a common cause of configuration errors and can cause unpredictable results.

SS7 TUP Configuration

8.1 Introduction to the TUP Layer  114
8.2 The TUP Configuration  116
8.3 Sample TUP Configuration File  117
8.4 TUP Configuration Parameters Reference  119
   8.4.1 General Parameters  119
   8.4.2 Service Access Point (SAP) Definition  122
   8.4.3 Network Service Access Point (NSAP) Definition  123
   8.4.4 Circuit/Group Definitions  124
8.1 Introduction to the TUP Layer

Like the ISUP layer, SS7 Telephone User Part (TUP) software provides an interface for applications to establish, maintain, and clear circuit switched connections via the SS7 network. The TUP layer is also responsible for circuit [group] management, such as blocking, unblocking, and resetting of circuits and circuit groups.

The SS7 TUP layer operates in accordance with the CCITT (ITU-T) recommendations Q.721-Q.724 and China GF001 - 9001 (Technical Specifications of SS7 for the National Telephone Network of China). TUP is not used in ANSI networks, so there is no applicable ANSI standard for TUP.

The configurable objects represented by the TUP layer are Circuits, User Service Access Points (User SAPs), and Network Service Access Points (NSAPs). In addition, the TUP layer has a set of general configuration parameters which define the behavior of the TUP layer as a whole.

Circuits are the physical bearer circuits controlled by the TUP layer. Like the ISUP layer, circuits are identified by both a circuit index and a circuit identification code (CIC). The circuit index is a number unique across all circuits configured on a particular TX board. This number has only local significance - it is used between the TUP layer and the local call processing application to identify a particular circuit.

The CIC (usually called the kick, or kick code) is used between signaling points (the SS7 TUP layer and the far exchange that terminates the other end of the circuit) to uniquely identify a particular circuit. The CIC must be configured at both ends of the circuit to identify the exact same bearer facility, for example, the same T1 span and timeslot. CICs need not be unique across circuits that terminate on different far exchanges.

Circuits are specified in the TUP configuration file in groups. A group is one or more circuits with contiguous circuit indexes and contiguous CICs that terminate on the same far exchange and have common characteristics. A single circuit group will frequently be used to represent all the timeslots on a single T1 or E1 span, for example. When defining a circuit group, only the circuit index and CIC of the first circuit in the group, along with the number of circuits in the group, are specified. The TUP layer derives the circuit index and CIC for subsequent circuits since they are considered to be contiguous. The starting circuit index and starting CIC for a group need not be the same value.
User SAPs define the interface between the TUP layer and the user applications.

**Note:** This release of the TUP layer supports only a single user application. Only one user SAP should be configured.

The NSAP defines the interface between the TUP layer and the MTP layer. It identifies the MTP network SAP to be used by the TUP layer, allowing multiple user parts (TUP, ISUP, and SCCP) to share access to the MTP layer services. Figure 10 illustrates the concept of user SAPs and NSAPs:

![Figure 10. TUP User SAPs and Network SAPs](image-url)
8.2 The TUP Configuration

The SS7 distribution software contains a utility program, `tupcfg`, which reads a text configuration file and downloads the specified configuration to the TUP task on the TX board, typically as part of the download sequence.

The general format of the TUP configuration file is provided here:

```xml
<General Configuration Parameters>
<User SAP definition>
<SAP Parameters>
END
<NSAP definition>
<NSAP Parameters>
END
<Circuit Group 1 definition>
<Circuit Group Parameters>
END
<Circuit Group n definition>
<Circuit Group Parameters>
END
```
8.3 Sample TUP Configuration File

The TUP distribution software contains sample configuration files for both ITU-T and China configurations. These configurations may be used in conjunction with the MTP sample configuration files to test TUP applications using two TX boards in a back-to-back arrangement (see Chapter 3). The following example shows the sample ITU-T configuration file for one board:

```
# TUP Configuration File

8.4 TUP Configuration Parameters Reference

There are five major sections of the TUP configuration file: general parameters, user SAP definition, network SAP definition, routes, and circuits.

8.4.1 General Parameters

The general parameters control the overall operation of the TUP layer process.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Default</th>
<th>Range</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAX_SAPS</td>
<td>1</td>
<td>1</td>
<td>Defines the maximum number of user applications.</td>
</tr>
<tr>
<td>MAX_NSAPS</td>
<td>1</td>
<td>1</td>
<td>Defines the maximum number of interfaces with the MTP 3 network layer.</td>
</tr>
<tr>
<td>MAX_CIRCUITS</td>
<td>96</td>
<td>0 to 65535</td>
<td>The maximum number of circuits to be managed by the TUP layer.</td>
</tr>
<tr>
<td>MAX_GROUPS</td>
<td>32</td>
<td>0 to 65535</td>
<td>The maximum number of circuit groups managed by the TUP layer.</td>
</tr>
<tr>
<td>MAX_DPCS</td>
<td>16</td>
<td>1 to 256</td>
<td>Defines the maximum number of destination point codes configured.</td>
</tr>
<tr>
<td>ALARM_LEVEL</td>
<td>1</td>
<td>1 to 4</td>
<td>In order to limit the number of alarms to the more critical ones, set this number closer to 1.</td>
</tr>
<tr>
<td>TRACE_EVENT</td>
<td>NO</td>
<td>YES</td>
<td>NO</td>
</tr>
<tr>
<td>TRACE_DATA</td>
<td>NO</td>
<td>YES</td>
<td>NO</td>

<tr>
<td>TIMER_TRACE</td>
<td>NO</td>
<td>YES</td>
<td>NO</td>
</tr>
<tr>
<td>CHECKPOINT_TYPE</td>
<td>YES</td>
<td>YES</td>
<td>NO</td>
</tr>
</tbody>
</table>

Note: This parameter is not required in standalone mode.
### MTP_PAUSE_TIMER

Specifies the maximum duration of an MTP3 pausetimer before clearing circuits associated with a DPC. The MTP3 pause timer starts when a pause is received from MTP3. When the pause timer expires, all the configured circuits associated with the DPC for which the pause is received are cleaned up. Setting the timer value to 0 disables this functionality.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Default</th>
<th>Range</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>MTP_PAUSE_TIMER</td>
<td>2</td>
<td>0 to 65535</td>

</tr>
</tbody>
</table>
8.4.2 Service Access Point (SAP) Definition

The SAP definition defines the characteristics of the TUP service presented to the user application(s).

*Note:* This release of the TUP layer software allows for configuration of only a single TUP user SAP. Only one application may use the TUP service at a time.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Default</th>
<th>Range</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>USER_SAP</td>
<td>none</td>
<td>0 to MAX_SAPS</td>
<td>SAP number.</td>

<td></td>
<td></td>
<td>Marks the end of the SAP section.</td>
</tr>
</tbody>
</table>
### 8.4.3 Network Service Access Point (NSAP) Definition

The NSAP definition defines the characteristics of the TUP interface to the MTP 3 layer.

**Note:** This release of the TUP layer software allows for configuration of only a single NSAP. Only one switch type may be handled at a time.

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Default</th>
<th>Range</th>
<th>Usage</th>

8.4.4 Circuit/Group Definitions

The circuit set definitions specify the characteristics of each of the circuit sets to be managed by the TUP layer. This includes the circuit identification codes (CICs) and destination point code (DPC) at the other end of the circuits. One entry is made for each circuit set. Any set can be designated as a predefined group by adding a group number to this definition. A predefined group can more easily be reset, blocked and unblocked with the API or by the network.

<table>
<thead>
<tr>
<th>Parameter Name</th>

SS7 TCAP Configuration

9.1 Introduction to the TCAP Layer 128
9.2 The TCAP Configuration File 129
9.3 TCAP Configuration Reference 130
   9.3.1 General Parameters Definition 131
   9.3.2 User Service Access Point (SAP) Definitions 133
9.1 **Introduction to the TCAP Layer**

The SS7 TCAP layer adds transaction services onto the connectionless data transfer service provided by the SCCP layer. Transactions in the SS7 network are typically database queries/responses or requests to activate services in remote switching points.

The SS7 TCAP layer can be configured for either ANSI (see ANSI T1.114) or ITU-T (see Q.771 - Q.775) operation, on a per-application basis. Use of ITU-T TCAP on top of an ANSI MTP/SCCP stack is fully supported. Use of the TCAP layer requires use (and proper configuration of) the SCCP and MTP layers.

The TCAP layer configuration consists of *general configuration parameters* and TCAP *User Service Access Points (SAPs)*. The general configuration parameters define the resource allocation for the TCAP layer: maximum number of user SAPs, maximum number of simultaneous dialogs, and maximum number of outstanding invokes.

User SAPs define the interface between a TCAP user application and the TCAP layer. One user SAP is defined for each application using the TCAP layer services. A user SAP is associated with a single subsystem number and protocol variant (ANSI-88, ANSI-92, ANSI-96, ITU-88, ITU-92, or ITU-97). Each TCAP user SAP maps directly to a SCCP user SAP in the SCCP configuration file (see Chapter 7), although not all SCCP SAPs must be assigned to TCAP applications; some applications may access the SCCP layer directly.

The relationship between TCAP user SAPs and SCCP user SAPs is illustrated in Figure 11.
9.2 The TCAP Configuration File

The TCAP distribution software contains an application (tcapcfg) which reads a text configuration file and downloads it to the TCAP layer on the TX board, typically as part of the boot sequence. A sample configuration file, tcapcfgn.cfg is included with the distribution software and is shown below.

Note: Not all configurable parameters need be specified in the configuration file. Most will default to reasonable values if not specified.
# Sample TCAP configuration file for the following configuration

**General:**
- 4 user APPs max
- 200 max simultaneous dialogs
- 200 max simultaneous invokes
- all others general defaults

**General Configuration Section**

- `TCAP_ALARM_LEVEL      1` # standard alarms
- `MAX_TCAP_USERS        4` # Max TCAP user applications
- `MAX_TCAP_DIALOGS      200` # Max TCAP simultaneous dialogs
- `MAX_TCAP_INVOKES      200` # Max TCAP simultaneous invokes

END

**User SAP configuration for 1st application**

- `USER_SAP              0` # Sap number start at 0
- `SWITCH_TYPE           ANSI92` # one of ITU92, ITU88, ANSI92, ANSI88

END # User application 0

**User SAP configuration for 2nd application**

- `USER_SAP              1` # Sap number start at 0
- `SWITCH_TYPE           ANSI92` # one of ITU92, ITU88, ANSI92, ANSI88

END # User application 0

**User SAP configuration for 3rd application**

- `USER_SAP              2` # Sap number start at 0
- `SWITCH_TYPE           ANSI92` # one of ITU92, ITU88, ANSI92, ANSI88

END # User application 0

**User SAP configuration for 4th application**

- `USER_SAP              3` # Sap number start at 0
- `SWITCH_TYPE           ANSI92` # one of ITU92, ITU88, ANSI92, ANSI88

END # User application 0

## 9.3 TCAP Configuration Reference

The following sections detail the configurable parameters for each configuration section.
9.3.1 General Parameters Definition

The general parameters configuration section defines the operational characteristics of the TCAP layer, mostly upper bounds for internal data structures (these determine the amount of memory used by the TCAP layer). It is the first section of the configuration file.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAX_TCAP_USERS</td>
<td>1 to 512</td>
<td>Maximum number of user SAPs. Default value is 4.</td>
</tr>
<tr>
<td>MAX_TCAP_DIALOGS</td>
<td>1 to 32767</td>
<td>Maximum number of TCAP transactions that may be pending at any one time. Default value is 256.</td>
</tr>
<tr>
<td>MAX_TCAP_INVOKES</td>
<td>1 to 32767</td>
<td>Maximum number of TCAP invoke operations that may be pending at any one time. Default value is 256.</td>
</tr>
<tr>
<td>MIN_TID_LEN</td>
<td>1 to 4</td>
<td>Forces use of transaction IDs of at least the specified number of bytes when using ITU-T TCAP; Primarily for interoperability with certain networks which require use of 4-byte transaction IDs. Default value is 1.</td>
</tr>
<tr>
<td>PC_FORMAT</td>
<td>DEFAULT, [DFLT], INTERNATIONAL [INTL], JNTT</td>
<td>Point Codes are interpreted/displayed as 24-bit 8.8.8 values. Point Codes are interpreted/displayed as 14-bit 3.8.3 values. Point codes are interpreted/displayed as 16-bit values in the following format: mcode.scode.ucode where the U-code occupies the most significant 7 bits, the S-code occupies the next 4 bits, and the M-code occupies the least significant 5 bits. Default value is DEFAULT.</td>
</tr>
<tr>
<td>TCAP_ALARM_LEVEL</td>
<td>0 to 3</td>
<td>The level of alarms to be generated by the TCAP layer: 0 = none (not recommended) 1 = service impacting events 2 = individual transaction impacting events (encode/decode errors) 3 = debugging level Default value is 1.</td>
</tr>
<tr>
<td>Field Name</td>
<td>Range</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>TCMEM_THRESH_1</td>
<td>1 to 99</td>
<td>Percentage of memory available in default message buffer pool below which congestion level 1 is triggered. Default value is 20.</td>
</tr>
<tr>
<td>TCMEM_THRESH_2</td>
<td>1 to 99</td>
<td>Percentage of memory available in default message buffer pool below which congestion level 2 is triggered. Must be less than TCMEM_THRESH_1. Default value is 15.</td>
</tr>
<tr>
<td>TCMEM_THRESH_3</td>
<td>1 to 99</td>
<td>Percentage of memory available in default message buffer pool below which congestion level 1 is triggered. Must be less than TCMEM_THRESH_2. Default value is 10.</td>
</tr>
</tbody>
</table>
9.3.2 User Service Access Point (SAP) Definitions

One user SAP is defined for each application/subsystem using the TCAP layer services. A user SAP is associated with a single subsystem number and switch type (ANSI88, ANSI92, ANSI96, ITU88, or ITU92, ITU97).

Note: Field names indicated in bold are only available with SS7 3.5 and later releases.

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>USER_SAP</td>
<td>0 to (MAX_USERS-1)</td>
<td>Marks start of a User SAP definition. User SAP numbers start at zero and are numbered sequentially up to MAX_USERS-1. There is no default value.</td>
</tr>
<tr>
<td>SWITCH_TYPE</td>
<td>ITU88, ITU92, ITU97, ANSI88, ANSI92, ANSI96</td>
<td>Protocol variant used on this SAP. Default value is ANSI92.</td>
</tr>
<tr>
<td>TCAP_T1</td>
<td>1 to 32767</td>
<td>Default invocation timer, in seconds (time to wait for response to invoke). Default value is 60.</td>
</tr>
<tr>
<td>TCAP_T2</td>
<td>1 to 32767</td>
<td>Time to wait for reject of a non-invoke component, in seconds, before considering operational successful (where applicable). Default value is 60.</td>
</tr>
<tr>
<td>TCAP_SEQ_TIMER</td>
<td>1 to 255</td>
<td>Duration to request SCCP to maintain SLS for when sequential delivery required. Default value is 60.</td>
</tr>
<tr>
<td>SCCP_SAP</td>
<td>0 to 32766</td>
<td>SCCP SAP ID (from SCCP config.) to map this TCAP SAP onto. By default, set to the same value as the TCAP SAP ID.</td>
</tr>
<tr>
<td>ALLOW_INVOKE_END</td>
<td>0 or 1</td>
<td>When set to 1, allows an Invoke component in an ITU-T End message. Default value is 0.</td>
</tr>
</tbody>
</table>
### Field Name | Range | Description
--- | --- | ---
SCCP_ADDR_OVERRIDE | 0 or 1 | SCCP called and calling addresses specified by a user application are ignored for the following messages:
- ITU-T: Continue, End, and User Abort
- ANSI: Conversation, Response, and User Abort
If set to 1, SCCP called and calling addresses specified by the user application are used for all affected messages. Default value is 0.

INACTIVITY_TIMER | 0 to 64535 | Default inactivity timer. Number of seconds before an inactivity indication is sent for a transaction with no traffic. If set to zero, the inactivity timer is disabled. Default value is 0.

DEFAULT_CHECKPOINT | CHKPT_NONE, CHKPT_SEND, CHKPT_ALL | Default checkpoint value. If set to CHKPT_ALL, all transactions are checkpointed to the backup TCAP task. If set to CHKPT_SEND, only transactions initiated by the TX board are checkpointed. If set to CHKPT_NONE, no transactions are checkpointed. Default value is CHKPT_NONE.

TCQ_THRESH_1 | 1 to 65535 | Number of inbound messages queued to the application before entering level 1 congestion. Default value is 600.

TCQ_THRESH_2 | 1 to 65535 | Number of inbound messages queued to the application before entering level 2 congestion. Must be greater than TCQ_THRESH_1. Default value is 900.

TCQ_THRESH_3 | 1 to 65535 | Number of inbound messages queued to the application before entering level 2 congestion. Must be greater than TCQ_THRESH_2. Default value is 1200.
Chapter 10

SS7 Software Download

10.1 Introduction 136
10.2 Sample ss7load Script for Windows NT/Windows 2000 138
10.3 Sample ss7load Script for UNIX Systems 142
10.1 Introduction

The SS7 distribution CD-ROM contains a sample script, `ss7load`, for downloading the SS7 software and configuration files to the TX board(s) for each operating system. The `ss7load` utility may be found in the following locations:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows NT/Windows 2000</td>
<td><code>\nms\tx\bin\ss7load.bat</code></td>
</tr>
<tr>
<td>UnixWare and Solaris</td>
<td><code>/opt/nmstx/bin/ss7load</code></td>
</tr>
</tbody>
</table>

The sample script takes a single parameter, the board number, which is required (On some operating systems this may default to board 1 if omitted). The following example shows the output of `ss7load` when run on Windows NT or Windows 2000:

```
prompt> ss7load 1
CPMODEL V1.0: Copyright 1998, NMS Communications
Board #1 is a TX2000
Loading: E.0 TX2000 Kernel (c)1996-1997 NMS Communications, Inc. 2/10/97
Loading: diag2000 Version C.1.0 12/10/97
Loading: inf Version C.4.0 12/10/97
Loading: mvip Version A.1.0 12/10/97
Loading: t1e1mgr Version A.1.0 12/10/97
Loading: mtp Version B.3.0 01/14/98
mtp2cfg: sample MTP2 configuration application version B.1.0 Jan 14 1998
mtp3cfg: sample MTP3 configuration application version B.3.0 Jan 14 1998
```

The exact contents of the `ss7load` script varies by operating system, but the basic functions executed by `ss7load` are as follows (the order is significant):

1. A utility program is executed to determine the model number of the board so that the correct operating system kernel may be downloaded. For PCI and Compact PCI boards, the kernel exists on flash.

   The `txflash` utility is used to reset PCI and Compact PCI boards. If the version of the operating system on the TX board’s flash memory does not match the version installed on the host system, the `txflash` utility automatically updates the board’s flash image before resetting the board.

2. The operating system kernel and related utility software modules are downloaded using the `cplot` loader utility.

3. The `mvip` and `t1e1mgr` tasks are downloaded to the board. These tasks enable use of the MVIP switching and T1/E1 configuration/control APIs. If
your system does not use these APIs, these commands may be removed from ss7load.

4. The SS7 MTP layer task (mtp.lot) is downloaded to the board. This task must be downloaded before any of the other SS7 software layers. This is the only required SS7 module.

5. Any optional SS7 layers which have been manually enabled are downloaded to the board.

6. The mtp2cfg (optional) and mtp3cfg (required) utilities are executed to download the MTP configuration to the MTP task. Again, the MTP layers must be configured before any of the other SS7 layers.

7. Any optional SS7 configuration utilities which have been enabled are executed to download their respective configurations to the appropriate SS7 layer task. Again, the order shown in the ss7load file should be maintained.

By default, the sample ss7load script installed with the SS7 MTP package downloads only the MTP software and configuration to the board. The commands to load and configure the other SS7 software layers (ISUP, TUP, SCCP, and TCAP) are present, but commented out.

Note: If you use any of these optional software layers, you must edit the ss7load script to enable the download and configuration of the applicable layers.

You may also want to modify the script to change the file and/or path names of the SS7 configuration files as you modify the sample configuration files to meet your system needs.

The following examples show the ss7load scripts for Windows NT/Windows 2000 and UNIX systems, respectively.

    DIAG="diag2000.lot"
    ;;
  *)
    echo "Board $BRD not available"
    exit 1
    ;;
esac

#**************************************************************************
# load CPK/OS and related tasks
#
if [ ! -z "$CPK" ]
then
  $TXUTIL/cplot -c $BRD -f $TXBASE/$CPK -k -u ss7 -a
```
# Make sure kernel load was successful

```bash
if [ $? -ne 0 ]
then
  echo "Kernel load failed, exiting $0 script"
  exit 1
fi
else
  $TXUTIL/txflash -s $TXBASE/$FLASH -b$BRD
fi
```

- Load related tasks
  - $TXUTIL/cplot -c $BRD -f $TXBASE/$DIAG -n diag -p 2 -a
  - $TXUTIL/cplot -c $BRD -f $TXBASE/inf.lot -n inf -p 16 -a

- load TDM configuration - note: remove this line if you use
  serial (V.35) ports rather than T1/E1/MVIP
  - $TXUTIL/cplot -c $BRD -f $TXCONFIG/TDMcp${BRD}.bin -g tdm

- load the MVIP and T1/E1 manager tasks to enable use
  of the MVIP and T1/E1 host APIs. Note: if you do not
  use either of these APIs, remove the following two lines
  - $TXUTIL/cplot -c $BRD -f $TXBASE/mvip.lot -n mvip -p 4 -a
  - $TXUTIL/cplot -c $BRD -f $TXBASE/t1e1mgr.lot -n t1e1mgr -p 15 -a

- To use txdbg, you should uncomment the following line to
  load the debug task
  - $TXUTIL/cplot -c $BRD -f $TXBASE/debug.lot -n debug -p 3 -a

- To enable packet tracing in the ISUP layer, make the following
  command active to load the ETP trace collector on the board
  - $TXUTIL/cplot -c $BRD -f $TXBASE/etp.lot -n etp -p 14 -a

- Load the ARP and TX Monitor tasks
  - $TXUTIL/cplot -c $BRD -f $TXBASE/arp.lot -n arp -p 20 -a
# ***** IMPORTANT NOTE *****
# For convenience we are loading TXMON only in redundant mode. This is
# convenient because MTP will detect the lack of TXMON and will
# automatically
# enter standalone mode and attempt to bring up the links, without
# application intervention. NOTE HOWEVER, TXMON can be used as a health
# monitor for a single board application in standalone mode. In this case
# the MTP will remain in a Starting state until an application (ie. RMG),
# using the HMI API, specifically sets the mode to Standalone. In other
# words links will not automatically try to align if TXMON is loaded.
#
if [ $TXMODE = "redundant" ]
then
    $TXUTIL/cplot -c $BRD -f $TXBASE/txmon.lot -n txmon -p 12 -a
fi
